## Problem Set #2 (BDAT 1004)

# By Daryoush Shabahang July 8, 2021

#### **Question 1 Python**

File idterm.py not found.

Consider the following Python module: a = 0def b(): global a a = c(a)def c(a): return a + 2 After importing the module into the interpreter, you execute: >>> b() >>> b() >>> b() >>> a What value is displayed when the last expression (a) is evaluated? Explain your answer by indicating what happens in every executed statement. MY ANSWER: In this scenario, a is defined as a global variable, then function b is making changes to it by calling function c to add 2 each time a is interpreted. For example, the value starts at 0, then after the first time a = 2, then the second time a = 4 and finally, the third time a = 6. Therefore, the final value evaluated will be 6 since function b i s called three times. **Question 2 Python** Function fileLength(), given to you, takes the name of a file as input and returns the length of the file: >>> fileLength('midterm.py') 284 >>> fileLength('idterm.py') Traceback (most recent call last): File "pyshell#34>", line 1, in module> fileLength('idterm.py') File "/Users/me/midterm.py", line 3, in fileLength infile = open(filename) FileNotFoundError: [Errno 2] No such file or directory: 'idterm.py' As shown above, if the file cannot be found by the interpreter or if it cannot be read as a text file, an exception will be raised. Modify function fileLength() so that a friendly message is printed instead: >>> fileLength('midterm.py') 358 >>> fileLength('idterm.py')

```
def fileLength(filename):
    # try to open the file
    try:
        file = open(filename)
            contents = file.read()
            print(len(contents))
            file.close()

# otherwise, this text is printed if the file name is incorrect or file is not found
    except FileNotFoundError:
            print("File", filename, "not found")

fileLength("idterm.py")
File idterm.py not found
```

### **Question 3 Python**

Write a class named Marsupial that can be used as shown below:

```
>>> m = Marsupial())
>>> m.put_in_pouch('doll')
>>> m.put_in_pouch('firetruck')
>>> m.put_in_pouch('kitten')
>>> m.pouch_contents()
['doll', 'firetruck', 'kitten']
```

Now write a class named Kangaroo as a subclass of Marsupial that inherits all the attributes of Marsupial and also:

a. extends the Marsupial \_\_init\_\_ constructor to take, as input, the coordinates x and y of the Kangaroo object, b. supports method jump that takes number values dx and dy as input and moves the kangaroo by dx units along the x-axis and by dy units along the y-axis, and

c. overloads the \_str\_ operator so it behaves as shown below.

```
>>> k = Kangaroo(0,0)
>>> print(k)
I am a Kangaroo located at coordinates (0,0)
>>> k.put_in_pouch('doll')
>>> k.put_in_pouch('firetruck')
>>> k.put_in_pouch('kitten')
>>> k.jump(1,0)
>>> k.jump(1,0)
>>> print(k)
I am a Kangaroo located at coordinates (3,0)
```

```
class Marsupial:
    def init (self):
         self.q = [] # initializing the class as an empty list
    def put in pouch(self, item):
         self.q.append(item) # appending items to the list
    def pouch contents(self):
        return self.q # returning the contents of the list
m = Marsupial()
m.put_in_pouch("doll")
m.put_in_pouch("firetruck")
m.put_in_pouch("kitten")
m.pouch contents()
class Kangaroo(Marsupial):
    def __init__(self, x_coordinate, y_coordinate):
        Marsupial. init (self)
        self.x_coordinate = x_coordinate
         self.y_coordinate = y_coordinate
    def jump(self, dx, dy):
        self.x_coordinate = self.x_coordinate + dx
self.y_coordinate = self.y_coordinate + dy
    def __repr__(self):
         return("I am a Kangaroo located at coordinates ({0},{1})".format(self.x coordinate, self.
k = Kangaroo(0,0)
print(k)
k.put_in_pouch("doll")
k.put in pouch("firetruck")
k.put_in_pouch("kitten")
k.pouch contents()
k.jump(1,0)
k.jump(1,0)
k.jump(1,0)
print(k)
I am a Kangaroo located at coordinates (0,0)
```

### **Question 4 Python**

I am a Kangaroo located at coordinates (3,0)

Write function collatz() that takes a positive integer x as input and prints the Collatz sequence starting at x. A Collatz sequence is obtained by repeatedly applying this rule to the previous number x in the sequence:

```
x = \{ x/2 \text{ if } x \text{ is even } \}
```

```
3x + 1 if x is odd
```

Your function should stop when the sequence gets to number 1. Your implementation must be recursive, without any loops.

```
>>> collatz(1)

1
>>> collatz(10)

10
5
16
8
4
2
1
```

```
def collatz(x):
    # this will check if x is a positive integer (i.e. greater than 1 or not)
    if(x) > 1:
        # this will round the number to ensure there aren't any decimals in the output
       print(round(x))
         if x is even, then the number will be divided by 2
        # and result will be stored in x, then calling the collatz function again
        if x % 2 == 0:
            x /= 2
            collatz(x)
        \# if x is odd, then the number will be multiplied by 3 + 1
        # and result will be stored in x, then calling the collatz function again
        else:
            x = x * 3 + 1
            collatz(x)
    \# otherwise if x is 1 or less than 1, then the output is only 1.
       print(1)
collatz(10)
10
16
4
2
```

#### **Question 5 Python**

Write a recursive method binary() that takes a non-negative integer n and prints the binary representation of integer n.

```
>>> binary(0)
>>> binary(1)
>>> binary(3)
>>> binary(9)
1001
 def binary(n):
     # if the value is less than 0, there will be an error
         if n < 0:
             raise ValueError(n)
         # otherwise, the output will print
         elif n > 1:
             binary(n // 2)
         print(n % 2,end = '')
     except ValueError:
         print("Only a non-negative number is permitted, please try again")
 binary(9)
1001
```

# **Question 6 Python**

Implement a class named HeadingParser that can be used to parse an HTML document, and retrieve and print all the headings in the document. You should implement your class as a subclass of HTMLParser, defined in Standard Library module html.parser.

When fed a string containing HTML code, your class should print the headings, one per line and in the order in which they

appear in the document.

Each heading should be indented as follows:

an h1 heading should have indentation 0, and h2 heading should have indentation 1, etc. Test your implementation using w3c.html.

- >>> infile = open('w3c.html')
- >>> content = infile.read()
- >>> infile.close()
- >>> hp = HeadingParser()
- >>> binary(3)
- >>> hp.feed(content)

W3C Mission

Principles

```
from html.parser import HTMLParser
class HeadingParser(HTMLParser):
    # initially an evaluation of each heading
   h1 check val = False
   h2 check val = False
   h3_check_val = False
    h4 check val = False
   h5 check val = False
   h6 check val = False
    def handle starttag(self, tag, attrs):
       if tag == "h1":
           self.hl check val = True
        if tag == \overline{h2}:
           self.h2 check val = True
        if tag == "h3":
           self.h3 check val = True
        if tag == "h4":
            self.h4_check_val = True
        if tag == "h5":
           self.h5_check_val = True
        if tag == \frac{1}{h}6":
            self.h6 check val = True
    # depending on the type of heading used, a tab with whitespace is added except for H1
    def handle data(self, data):
       if(self.h1 check val):
            print(data)
            self.h1_check_val = False
        if(self.h2_check_val):
            print("\t" * 2 + data)
            self.h2_check_val = False
        if(self.h3_check_val):
           print("\t" * 3 + data)
            self.h3_check_val = False
        if(self.h4_check_val):
            print("\t" * 4 + data)
            self.h4_check_val = False
        if(self.h5_check_val):
            print("\t" * 5 + data)
            self.h5_check_val = False
        if(self.h6 check val):
            print("\t" * 6 + data)
            self.h6_check_val = False
infile = open("w3c.html")
content = infile.read()
infile.close()
headingParser = HeadingParser()
headingParser.feed(content)
```

W3C Mission Principles

## **Question 7 Python**

Implement recursive function webdir() that takes as input:

a URL (as a string) and non-negative integers depth and indent.

Your function should visit every web page reachable from the starting URL web page in depth clicks or less, and print each web page's URL.

As shown below, indentation, specified by indent, should be used to indicate the depth of a URL.

webdir('http://reed.cs.depaul.edu/lperkovic/csc242/test1.html', 2, 0) http://reed.cs.depaul.edu/lperkovic/csc242/test1.html http://reed.cs.depaul.edu/lperkovic/csc242/test2.html http://reed.cs.depaul.edu/lperkovic/csc242/test4.html http://reed.cs.depaul.edu/lperkovic/csc242/test3.html

1 1 // 1 1 1 / 040 // (41)

```
from urllib.request import urlopen
from urllib.parse import urljoin
from html.parser import HTMLParser
class Collector(HTMLParser):
    def init (self, url):
       HTMLParser.__init__(self)
        self.url = \overline{url}
        self.links = []
    def handle_starttag(self, tag, attrs):
        if tag == "a":
            for attr in attrs:
                if attr[0] == "href":
                    absolute = urljoin(self.url, attr[1])
                    if absolute[:4] == "http":
                        self.links.append(absolute)
    def getLinks(self):
        return self.links
visited = set()
def webdir(url, depth, indent):
   global visited
   visited.add(url)
    links = analyze(url)
    for link in links:
       if link not in visited:
           try:
               print('',link)
            except:
               print(link)
webdir("http://reed.cs.depaul.edu/lperkovic/one.html", 2, 0)
http://reed.cs.depaul.edu/lperkovic/two.html
```

#### Question 8 SQL

Write SQL queries on the below database table that return:

http://reed.cs.depaul.edu/lperkovic/three.html

- a) All the temperature data.
- b) All the cities, but without repetition.
- c) All the records for India.
- d) All the Fall records.
- e) The city, country, and season for which the average rainfall is between 200 and 400 millimeters.
- f) The city and country for which the average Fall temperature is above 20 degrees, in increasing temperature order.
- g) The total annual rainfall for Cairo.
- h) The total rainfall for each season.

I am first creating the table and displaying it since the table doesn't yet exist. Then I will answer each question.

I learned how to connect SQL with Jupyter Notebook by using these two resources:

https://www.datacamp.com/community/tutorials/sql-interface-within-jupyterlab

https://towardsdatascience.com/how-to-run-sql-queries-from-a-jupyter-notebook-aaa18e59e7bc

```
%%sal
 CREATE TABLE various cities
         City varchar(25),
Country varchar(25),
Season varchar(10),
        City
         Temperature float,
         Rainfall float
  );
  INSERT INTO various cities
  VALUES ('Mumbai', 'India', 'Winter', 24.8, 5.9),
               ('Mumbai', 'India', 'Spring', 28.4, 16.2),
('Mumbai', 'India', 'Summer', 27.9, 1549.4),
                ('Mumbai', 'India', 'Fall', 27.6, 346.0),
                ('London', 'United Kingdom', 'Winter', 4.2, 207.7), ('London', 'United Kingdom', 'Spring', 8.3, 169.6),
                 ('London', 'United Kingdom', 'Summer', 15.7, 157.0),
                 ('London', 'United Kingdom', 'Fall', 10.4, 218.5),
                ('Cairo', 'Egypt', 'Winter', 13.6, 16.5), ('Cairo', 'Egypt', 'Spring', 20.7, 6.5), ('Cairo', 'Egypt', 'Summer', 27.7, 0.1),
                 ('Cairo', 'Egypt', 'Fall', 22.2, 4.5);
  * sqlite://
Done.

                                      1549.4
Mumbai
Mumbai
          India
                    Fall
                                27.6
                                       346.0
```

#### Question 8d SQL

d) All the Fall records.

```
%%sql
{\bf FROM} \ {\tt various\_cities}
WHERE season = 'Fall';
 * sqlite://
               Country Season Temperature Rainfall
   City
Mumbai
                   India
                             Fall
                                          27.6
                                                  346.0
London United Kingdom
                             Fall
                                          10.4
                                                  218.5
  Cairo
                  Egypt
                             Fall
                                          22.2
                                                    4.5
```

#### Question 8e SQL

e) The city, country, and season for which the average rainfall is between 200 and 400 millimeters.

```
In [83]:

SELECT city, country, season, rainfall
FROM various_cities
WHERE rainfall BETWEEN 200 AND 400;

* sqlite://
Done.

Out[83]:

City Country Season Rainfall
Mumbai India Fall 346.0

London United Kingdom Winter 207.7

London United Kingdom Fall 218.5
```

### Question 8f SQL

f) The city and country for which the average Fall temperature is above 20 degrees, in increasing temperature order.

# Question 8g SQL

g) The total annual rainfall for Cairo.

```
In [85]: %%sql

SELECT city, sum(rainfall) AS Total_Annual_Rainfall
FROM various_cities
WHERE city = 'Cairo';

* sqlite://
Done.

Out[85]: City Total_Annual_Rainfall
Cairo 27.6
```

#### Question 8h SQL

h) The total rainfall for each season.

# **Question 9 Python**

Suppose list words is defined as follows:

>>> words = ['The', 'quick', 'brown', 'fox', 'jumps', 'over', 'the', 'lazy', 'dog']

Write list comprehension expressions that use list words and generate the following lists:

```
In [87]: # a) ['THE', 'QUICK', 'BROWN', 'FOX', 'JUMPS', 'OVER', 'THE', 'LAZY', 'DOG']
            words = ['The', 'quick', 'brown', 'fox', 'jumps', 'over', 'the', 'lazy', 'dog']
            listA = [x.upper() for x in words]
            print(listA)
            # b) ['the', 'quick', 'brown', 'fox', 'jumps', 'over', 'the', 'lazy', 'dog']
            listB = [x.lower() for x in words]
            print(listB)
            # c) [3, 5, 5, 3, 5, 4, 3, 4, 3] (the list of lengths of words in list words).
            listC = [len(x) for x in words]
            print(listC)
            # d) [['THE', 'the', 3], ['QUICK', 'quick', 5], ['BROWN', 'brown', 5], ['FOX', 'fox', 3], ['JUMPS
            # ['OVER', 'over', 4], ['THE', 'the', 3], ['LAZY', 'lazy', 4], ['DOG', 'dog', 3]]
            # (the list containing a list for every word of list words, where each list contains the word in
            # and the length of the word.)
            listD = [[x.upper(), x.lower(), len(x)] for x in words]
            print(listD)
            # e) ['The', 'quick', 'brown', 'fox', 'jumps', 'over', 'the', 'lazy', 'dog']
            # (the list of words in list words containing 4 or more characters.)
            listE = [x for x in words if len(x) >= 4]
            print(listE)
            # Please note: in the PDF, it shows a lot more words, but the only words with 4 or more character
            # output ("quick", "brown", "jumps", "over", "lazy")
           ['THE', 'QUICK', 'BROWN', 'FOX', 'JUMPS', 'OVER', 'THE', 'LAZY', 'DOG']
['the', 'quick', 'brown', 'fox', 'jumps', 'over', 'the', 'lazy', 'dog']
[3, 5, 5, 3, 5, 4, 3, 4, 3]
[['THE', 'the', 3], ['QUICK', 'quick', 5], ['BROWN', 'brown', 5], ['FOX', 'fox', 3], ['JUMPS', 'jumps', 5], ['OVER', 'over', 4], ['THE', 'the', 3], ['LAZY', 'lazy', 4], ['DOG', 'dog', 3]]
['quick', 'brown', 'jumps', 'over', 'lazy']
           %load_ext sql
           %sql sqlite://
```
